

Narrative Arc

SECTION 1 — THE PROBLEM

The intent is there. The investments are real. The assets exist. The demand is present.

The outcomes keep falling short.

Not a shortage of solutions. A shortage of conditions that enable them to connect and scale.

SECTION 3 — THE PRECEDENT

This shift has happened before.

The internet didn't build websites. It built the protocol that let anyone build anything.

GPS didn't build navigation. It built the layer everything else grew from.

Mobile networks didn't build services. They built a common standard that let any device, any provider, any service connect to any other. The network works because the standard is open, not because anyone controls it.

In each case the shift was the same. From building solutions, to creating the conditions for solutions to emerge.

Urban Web brings that shift to cities.

SECTION 4 — THE AGENDA

Every city is working toward the same horizon. Cleaner, fairer, more liveable.

Urban Web doesn't add to that agenda. It changes the conditions under which it becomes achievable.

SECTION 5 — FOUR STORIES

Every city has different priorities. Every city has the same underlying opportunity. Here are FOUR ways pioneering cities are already seeing this differently.

When the daily commute becomes a city asset

Cities have modal shift targets. Most of the lever sits in the daily commute. What if every employer in your city could run a verified, auditable sustainable commute programme across every transit operator without a single bilateral agreement? And what if every trip became proof the city could use?

Read the story →

When mobility finds people instead of waiting for them

Cities spend billions on mobility infrastructure. Most of it waits to be found. The patient confirming an appointment, the employee seeing a shift, the event-goer buying a ticket, each

left to find their own way. What if mobility was already present at the moment the journey was decided?

Read the story →

When every parking space becomes a city resource

Every city has spaces sitting idle and demand that cannot find them. The supply is there. The connections are not. What if every space, public, private, basement, residential, was visible, bookable, and connected to the city around it?

Read the story →

When driving becomes aspirational

Cities are committing to electric fleets. But the transition depends on something no city can currently plan for: whether the workforce is ready.

Today a driver's skill and experience are invisible beyond the company they work for. Young people don't choose driving because there is no visible career path. Operators can't find qualified drivers for new electric fleets. Cities set electrification targets without knowing if the people to deliver them exist.

What if a city could see where its skills gaps are before they become a crisis? What if driving became a career where skill is recognised, rewarded, and worth investing in?

The cities that solve this first will transition fastest.

[Read the story →]

SECTION 6 — THE INVITATION

The cities that move first shape what comes next. The rest inherit what they build.

[I want to learn more] [My city wants to participate]

Employee Transport

From building corporate sustainability programmes to

Making Sustainable Commuting a City-Wide Capability

The Problem

A major employer in a city wants to make sustainable commuting a credible part of its ESG commitments, not just a policy on paper.

CONTEXT

Commuting is one of the largest and most addressable sources of employee-related emissions, and one of the hardest to act on at scale. But the problem does not belong to the employer alone:

- a city transport authority wants to know whether its public transit investment is actually shifting how people travel, but has no verified data to show it
- a transit operator wants to reach the corporate commuter market, but has no direct channel to employers or their employees
- an employer wants to prove that commute behaviour changed, but can only estimate from surveys
- a carbon market or monitoring agency needs auditable proof that emissions reduced, but receives self-reported data it cannot verify
- an employee wants to be recognised and rewarded for the right choice, but has to file a claim to get reimbursed

Today, each employer builds its own solution:

- negotiating separately with transit operators
- designing its own incentive programme
- estimating emissions from surveys and self-reporting
- reporting against frameworks that demand verified proof that is hard to produce

Every city has this problem. Every employer is solving it alone. And the city gets nothing from the work done.

THE INTEGRATION CHAIN

 Employer →  MaaS App ↳ Requests custom ESG tracking feature	CUSTOM
 MaaS App →  City Transit ITS ↳ Builds bespoke data connection	CUSTOM
 ITS →  Employer System ↳ Exposes custom trip verification API	CUSTOM

THE COST OF THIS APPROACH

Brittle by design Change any one system and the chain breaks. Every update requires renegotiation.	Works for one, locked for all This serves one employer, one app, one city. No one else benefits from the work done.	Enormous duplication Every employer starts from scratch. Every city rebuilds the same plumbing independently.
---	--	--

What If?

Verifiable sustainable commuting was a shared city-wide capability — available to every employer, across every operator, in every city on any platform / app / channel.

TODAY	THE WAY IT COULD WORK
✗ Each employer builds its own transit incentive programme from scratch	✓ One shared capability. Any employer connects. Any operator qualifies.
✗ Commute emissions estimated from surveys and self-reporting	✓ Every verified trip attributed to a verified employee. Automatically.
✗ Claiming carbon credits without proof of modal shift is a challenge	✓ Credits issued only on verified trip completion. Auditable. Reportable.
✗ HR manages travel receipts and reimbursements manually	✓ Settlement is automatic. No claims process. No admin overhead.
✗ ESG report built on assumptions	✓ ESG report built on verified trip data — reportable to any framework.

HOW WOULD THIS WORK

01 THE EMPLOYER SETS THE RULES ONCE

Which modes qualify. Which cities. Which employees. Time windows. Spend limits. Set once, applied everywhere, automatically. The employer never renegotiates with an operator. The rules follow every employee, across every city, from the moment they are set.

Any city | **Any operator** | **Any employee**

02 EVERY OPERATOR GAINS DEMAND THEY NEVER HAD TO NEGOTIATE FOR

Any verified transit operator in the city is automatically available to every employee in every qualifying programme. Operators do not need a relationship with any employer. They compete for corporate commuter demand on equal terms. The employee chooses freely. The best service wins.

No lock-in | **Open competition** | **Employee choice**

03 EVERY TRIP BECOMES EVIDENCE

Anonymised, aggregated, auditable. The employer gets proof. The city gets modal shift data. A health insurer gets verified active commute records. A carbon market gets proof, not declaration. Each actor extracts what it needs from the same record, without anyone building a separate pipeline. This shared layer is also what makes agentic AI possible at city scale.

Privacy by design | **Auditable outcomes** | **Agents act autonomously**

UNLOCKING USE CASES NOBODY PLANNED

WHO	THE MOMENT	WHAT OPEN NETWORKS ENABLE
 Any Employer	<i>ESG target set</i>	Commute emissions measured.No custom integration needed.
 Employee	<i>Trip completed</i>	Mobility vouchers or credit received automatically. Redeemable across any operator on the network.
 Carbon Market	<i>Credit claimed</i>	Verified, auditable trip data flows into carbon registries. Proof, not declaration.
 Health Insurer	<i>Active commute verified</i>	Active commuting rewarded using the same verified trip data. No new pipeline needed.
 City Government	<i>Policy target set</i>	Modal shift tracked across all employers and operators. Evidence base for investment.

 Corporation (CSR) / Other Grants	<i>Grant disbursed</i>	Mobility vouchers funded for low-income residents, elderly, or students — issued through the city's open network. No new programme to design. No separate distribution mechanism to build. Corporate sustainability and city equity delivered through the same infrastructure.
---	------------------------	--

WHAT THIS CHANGES

The employer stops building and starts connecting. Any employer in any city can verify commute behaviour, deploy incentives, and report outcomes across every operator, without a single bilateral agreement or custom integration.

The sustainable choice becomes the rewarded choice. Mobility credits arrive the moment the trip completes. No application. No reimbursement form. The employee is recognised for the right choice at the moment it is made.

The city gains intelligence it has never had, and it compounds with every participant that joins. When every employer's commute trips are verified on a shared layer, the city sees how its workforce actually moves. Which corridors carry corporate demand. Which communities are underserved. Planning intelligence extracted as a by-product of what employers needed for themselves. And as more actors join, that intelligence deepens. A health insurer joins and active commute data becomes a wellness instrument. A climate fund joins and modal shift becomes a disbursement trigger. Each new participant creates value for every actor already in the network.

Agentic AI becomes possible when the infrastructure is shared. An agent working on behalf of an employer monitors qualifying trips, attributes outcomes, and adjusts incentives across thousands of employees in multiple cities, with no HR involvement after setup. An agent working on behalf of a city reads aggregate modal shift patterns and adjusts public transport deployment in response. Neither requires human intervention at each step. Both are only possible when the underlying data is on a shared layer.

Parking

Unlock Parking for a City.

From Idle Space to Active City Resource.

Spaces exist across every city — in basements, behind offices, around residential blocks — yet to be discovered.

The Problem

A property owner in the city has thirty parking spaces sitting empty between 9am and 6pm every weekday. The owner wants to put them to use, but has no way to make them visible to the drivers or businesses who need them.

CONTEXT

Urban parking is one of the most fragmented services in any city:

- public and private parking exist in entirely separate silos with no shared visibility
- private parking apps and services do not cater to all customer segments — leaving gaps in coverage that no single operator has an incentive to fill.
- the competition among private parking operators has reduced the trust needed to combine inventory, each platform protects its supply rather than sharing it.
- property owners with unused spaces, on-street bays, basements, office lots, residential blocks, hotels, have no simple way to make them available to the public

Every city has this problem. Every owner is dealing with it alone.

THE INTEGRATION CHAIN

 Property Owner →  Parking App ↳ Lists spaces on a single proprietary platform	CUSTOM
 Parking App →  Navigation / Discovery ↳ Separate data deal per app to gain visibility	CUSTOM
 Navigation App →  Payment System ↳ Custom payment integration per operator	CUSTOM
 Payment System →  City Compliance ↳ Manual permit and compliance reporting per asset	CUSTOM

THE COST OF THIS APPROACH

Fragmented by design Public and private parking operate in separate silos. No shared picture. Owners carry the burden of listing on every platform separately.	Winner-take-all dynamics Private parking apps race for market dominance rather than coverage. The competition reduces trust and prevents operators from combining inventory — even when doing so would serve the city better.	Excluded by default Private services serve the segments they find profitable. Underserved areas, informal spaces, and smaller property owners remain outside digital systems entirely..
--	---	---

WHAT IF?

Every unused space in a city, in a basement, behind a shop, beneath a residential block, was visible and accessible to any user across the city..

TODAY	THE WAY IT COULD WORK
✗ A property owner's unused spaces generate no value	✓ Any unused space listed once becomes a programmable digital asset — discoverable, bookable, and capable of generating yield without active management.
✗ Private apps serve only their own inventory and customer segments	✓ Every space, every owner, every segment on one shared layer — no exclusions
✗ Pricing set in isolation, disconnected from actual demand	✓ Pricing responds to real-time availability across the full city
✗ A park-and-ride has no connection to the transit leg that follows	✓ Parking and onward transit booked and paid as one journey
✗ Compliance and reporting handled manually per asset	✓ Every transaction on record. Policy enforced through the shared layer automatically

HOW WOULD THIS WORK

01 EVERY PARKING SPACE ENTERS A SHARED LAYER

Any owner, from a municipality to a residential building, hospitals or malls, lists their spaces once on their own terms. From that point, every driver, every app, and every fleet operator in the city can find them. No bilateral agreements. No intermediary required.

Any space | Any owner | Any city

02 EVERY PARKING SPACE COMPETES ON SERVICE, NOT ON ACCESS

Access is open to all. No operator controls who participates, no driver is tied to one platform. Competition moves entirely to the quality of the space and the service.

No lock-in | **Open competition** | **Better outcomes for drivers**

03 PARKING BECOMES A LEVER FOR CITY-WIDE MOVEMENT

A congestion charge in one zone, a green access window in another, a logistics bay by time of day. The city does not need to own the spaces to govern them. Because every space, every transaction, and every demand signal is on a shared layer, AI agents can participate in a citywide parking network as active actors. An agent working on behalf of a driver can discover, negotiate, and transact across every available space in the city. An agent working for a property owner can respond to demand, adjust terms, and settle transactions with other agents and humans in real time. Shared infrastructure is the precondition for agentic AI to work at city scale.

Decentralised | **Autonomous** | **City-wide coordination**

Scenarios

- A hospital that wanted to reduce car park pressure discovered it could monetise idle capacity at weekends to visitors from across the city.
- A city that wanted to cut congestion discovered it could link prices to real-time demand without owning the spaces.
- A transit authority that wanted more park-and-ride users discovered it could bundle parking and the transit leg into one transaction.
- A property developer discovered that parking floors could be tokenised, fractionally owned, and automatically leased, generating yield without a property manager.

None of these were designed in. They became possible because the infrastructure was open to all. And the value each participant receives grows with every other participant that joins, without any of them coordinating directly.

UNLOCKING USE CASES NOBODY PLANNED

WHO	THE MOMENT	WHAT BECOMES POSSIBLE
 City Government	<i>Congestion target set</i>	Every space in the city visible and coordinated. Prices respond to demand. Drivers guided before they arrive. Circling stops without an enforcement operation.
 Property Owner	<i>Spaces sitting idle</i>	Unused spaces listed instantly. Demand arrives without a platform relationship. Revenue tracked in real time.
 Driver	<i>Searching for parking</i>	Full picture of every available space nearby. Live pricing. Booked before arrival.

 Transit Authority	<i>Park-and-ride underused</i>	Parking and transit booked as one journey. Demand grows without a campaign.
 EV Fleet Operator	<i>Charging across locations</i>	Parking and charging discoverable as one asset. Settled on verified energy delivery.
 Logistics Operator	<i>Finding a verified bay</i>	Time-windowed kerb bays bookable before the trip begins. Compliance without enforcement.
 Investor / Owner	<i>Asset underperforming</i>	Parking spaces tokenised into digital assets. Fractional ownership enabled. Automated leasing via smart contracts. Idle capacity generates yield without active management.

WHAT THIS CHANGES

The city sees its parking supply as a single living system for the first time. Zone-level demand, utilisation patterns, and policy response all visible in aggregate and in real time. The city can test a pricing intervention in one zone today and read the effect tomorrow. Urban parking becomes a policy instrument for managing congestion and unlocking value from assets the city does not need to own.

Physical infrastructure enters the digital economy. Every space on the shared layer can generate yield, connect to green finance instruments, and be managed without active ownership. Infrastructure that was a cost centre becomes productive, without the owner doing anything beyond listing once.

Every participant makes the network more valuable for everyone already in it. A hospital lists its car park and transit operators gain a demand channel they never had. A logistics operator lists time-windowed bays and EV operators can plan charging and parking together. The city becomes more capable with every addition, without additional investment or coordination.

Agentic AI becomes possible when the infrastructure is shared. On a shared layer, AI agents are not just automation tools. They are active participants. An agent working for a driver discovers, negotiates, and transacts across every available space in the city. An agent working for a property owner responds to other agents and humans in real time, managing demand and settling transactions without the owner intervening. This is only possible when the infrastructure is open. Closed platforms keep data and capability siloed. Shared infrastructure makes both available to every participant and every agent acting on their behalf.

Mobility as a Feature

WHAT MAAS WAS ALWAYS TRYING TO SOLVE.

From Mobility as a Service to Mobility as a Feature.

Every city has mobility infrastructure. Most travel decisions are made in places mobility has never reached.

The Problem

Cities commit billions to mobility infrastructure every year. Most of it sits underused.

Building mobility infrastructure, the buses, metros, and shared mobility services, is the easy part. The decision to use them or not happen while going to work, booking a hospital appointment, or buying an event ticket. Places mobility services have never been.

CONTEXT

Travel is derived demand. People travel because of a job, an appointment, an event, a concert, a home. The purpose comes first. The mobility decision follows. MaaS optimised the journey. It never entered the moment the journey was decided.

MaaS is the next generation, a shift from a multi-modal perspective to a multi-service one. Mobility embedded in the moment of decision, not waiting to be discovered after it.

A hospital confirms an appointment. A venue sells a ticket. An employer schedules a shift. In each case, the journey is left to the traveller to figure out alone.

- cities have built dedicated apps and platforms to bridge this gap, which struggle to gain the adoption needed to make them useful
- every connection between a mobility operator and a service is built bilaterally, from scratch, for one use at a time

Every city is investing in infrastructure that arrives too late — after the decision, not at it.

THE INTEGRATION CHAIN

 Event Organiser →  MaaS App ↳ Requests transit integration for ticket buyers	CUSTOM
 MaaS App →  Transit Operator ↳ Builds bespoke booking connection per operator	CUSTOM
 Transit Operator →  Ticketing System ↳ Exposes custom trip confirmation API	CUSTOM
 Ticketing System →  Payment Gateway ↳ Separate billing and settlement per operator	CUSTOM

THE COST OF THIS APPROACH

Built for the willing Mobility only reaches people who actively seek it out. The patient, the hotel guest, the event attendee, each is left to find their own way.	Works for one, locked for all This integration serves one hospital, one app, one city. A hotel, a retailer, or an event venue must each start from scratch.	Enormous duplication Every platform in every city rebuilds the same connections to the same operators, independently, at the same cost.
--	---	---

What If?

Mobility was a feature of every platform already in use in the city — present at the moment the decision is made, not after.

TODAY	THE WAY IT COULD WORK
✗ A traveller plans a journey across separate apps and services	✓ The journey appears inside the app they are already using
✗ A hospital arranges patient transport separately from care	✓ Transport is offered at the moment of appointment confirmation
✗ A transit operator runs half-empty buses with no demand signal	✓ Operators receive demand from every connected platform in the city
✗ A city builds a dedicated mobility app nobody downloads	✓ The city opens its infrastructure to every platform that wants to connect
✗ Mobility investment produces no measurable behaviour change	✓ Every trip verified, attributed, and reportable

HOW WOULD THIS WORK

01 THE CITY MAKES ITS MOBILITY DISCOVERABLE

Every operator — bus, metro, shared bike, informal transit — publishes the services. Any service, at any moment, can surface relevant mobility options for its users. No bilateral agreements. No proprietary systems required.

Any operator | **Any mode** | **Any city**

02 MOBILITY BECOMES PART OF THE DECISION, NOT A SEPARATE ONE

A hotel booking includes the airport transfer. A hospital appointment triggers a ride. An event ticket bundles the transit leg. An employer platform manages the commute. None of these platforms built a mobility product. They connected to the shared infrastructure — and mobility came with it.

Embedded | **No new app** | **Works where users already are**

03 MOBILITY SERVICES REACH PLACES THEY COULD NEVER ACCESS BEFORE

Operators gain demand channels they never negotiated for. A transit operator gains riders from a retailer's checkout. A shared bike operator gains bookings from a hotel confirmation. Because every trip, every demand signal, and every service interaction is on a shared layer, AI agents can act as participants in their own right. An agent working on behalf of a traveller assembles the entire journey across modes and purposes, negotiating and transacting autonomously. An agent working on behalf of a service responds to a confirmed appointment and dispatches the right journey option without human intervention at each step. Shared infrastructure is the precondition for agentic mobility to work at city scale.

No lock-in | **Open competition** | **Better service for travellers**

Scenarios

- A retailer that wanted to increase footfall discovered it could offer a transit leg with every online order.
- An event organiser that wanted to reduce venue congestion discovered it could bundle the transit leg with every ticket sold.
- A bank that wanted to reward sustainable behaviour discovered it could issue mobility credits redeemable across every operator in the city.
- A hospital that wanted to reduce missed appointments discovered it could offer a verified journey at the moment of confirmation — at no additional integration cost.

None of these were designed in. They became possible because the infrastructure was available to all.

UNLOCKING USE CASES NOBODY PLANNED

WHO	THE MOMENT	WHAT BECOMES POSSIBLE
 Hospital	<i>Appointment confirmed</i>	Patient transport offered at confirmation. Arrival rate improves. Car park pressure reduces.
 Hotel	<i>Booking completed</i>	Airport transfer included. City transit surfaced. Guest experience starts before check-in.
 Employer	<i>Shift scheduled</i>	Verified commute options offered at confirmation. ESG data generated. No corporate shuttle needed.
 Retailer	<i>Checkout completed</i>	Journey home offered at point of purchase. Loyalty credit applied to transit fare.
 Event Organiser	<i>Ticket purchased</i>	Transit leg bundled. Venue congestion reduced. Carbon footprint measurable.
 Bank	<i>Spending milestone reached</i>	Mobility credit issued. Redeemable across any operator in the city.
 Food / Delivery App	<i>Event ticket purchased</i>	Pre-order at venue or en route bundled with the transit leg. One checkout. Journey and meal confirmed together.
 Carbon Market	<i>Trip completed</i>	Every verified sustainable trip generates auditable carbon credits. No manual reporting. Proof, not declaration.
 City / Employer	<i>Sustainable trip completed</i>	Points, rewards, and challenges tied to verified travel behaviour. Sustainable choices become a game, not an obligation.
 EV Network	<i>Journey booked</i>	Charging stops surfaced and bookable as part of the journey. Mobility and energy settled in one transaction.
 Green Bond Issuer	<i>Modal shift verified</i>	Aggregated, verified trip data across employers and cities becomes the underlying asset for a green bond. The city borrows against behaviour change it can now prove.
 Informal Operator	<i>First trip completed</i>	A matatu driver, an auto-rickshaw, a motorcycle taxi — visible, bookable, receiving digital payments for the first time. Their mobility history becomes their business identity.

WHAT THIS CHANGES

The city stops building platforms and starts building leverage. One infrastructure decision. Every service in the city, every hospital, hotel, retailer, and event organiser, becomes a mobility distribution channel. The city does not chase travellers. It meets them where they already are.

The sustainable choice becomes the default. A dedicated app asked people to change their behaviour. This removes the ask. Mobility is already part of the decision being made — at the moment it matters most.

The network grows without the city managing it. A retail supermarket chain joins and every transit operator in the city gains a demand channel they never negotiated for. An event organiser bundles a transit leg and shared mobility service becomes bookable. The city becomes more capable with every addition, without additional investment or coordination from anyone.

Driver Network

THE WORKFORCE CITIES CANNOT SEE

Building A Connected And Skilled Driver Workforce

Cities are planning electric fleets. Operators need qualified drivers. Neither can see if the workforce is ready.

The Problem

A city has committed to electrifying its public transit fleet. It needs EV-certified drivers across multiple operators. It has no way to know how many exist, where they are, or whether the workforce will be ready when the vehicles arrive.

CONTEXT

Behind every bus, truck, cab, and school van is a driver. Drivers are the backbone of every city's mobility ecosystem. And yet the skills, experience, and compliance records that define a driver's capability are invisible the moment they leave one employer for another. The problem does not belong to the operator alone:

- a city planning an electrification transition cannot see its workforce readiness. Skills gaps are invisible until they become crises
- an operator needs to hire qualified drivers but has no way to verify training, employment history, or compliance records without rebuilding the process from scratch
- a driver who has spent years building strong and reliable experience has no way to carry that reputation forward. Invisible experience cannot command better wages or open better opportunities
- a training institute produces qualified candidates with no direct channel to the operators who need them
- a young person considering driving as a profession sees no visible career path where skill is recognised and rewarded

Today, each operator builds its own hiring and verification process:

- relying on personal networks, informal recruiters, or word of mouth to find candidates
- manually chasing certificates, calling previous employers who may not respond
- running police verification and medical checks independently for every candidate
- making hiring decisions on instinct because no trusted shared record exists

Every city has this problem. Every operator is solving it alone. And the driver gets nothing portable from the work done.

THE HIRING CHAIN TODAY

 Operator →  Personal Network / Recruiter ↳ Vacancy filled through informal channels. No verified candidate pool.	MANUAL
 Candidate arrives →  Document collection ↳ Operator manually requests license, certificates, previous employment records	MANUAL
 Documents →  Previous employer ↳ Operator calls previous employers. Often unresponsive. Records unverifiable.	MANUAL
 Police verification →  Medical check ↳ Run independently by every operator for the same pool of drivers	MANUAL

THE COST OF THIS APPROACH

Invisible by design A driver's skills, training, and clean record exist only within the company that holds them. They do not travel. Every operator starts from zero.	Rebuilt from scratch Every operator repeats the same verification process for the same pool of drivers. The same certificates chased, the same calls made, the same checks run.	No career path visible Without portable, trusted credentials, driving offers no visible progression. Young people do not choose it. Experienced drivers cannot command what they have earned.
---	---	---

What If?

A driver's verified credentials, training completed, employment history, compliance checks, and medical fitness, travelled with the driver. Visible to any operator. Built once. Trusted everywhere.

TODAY	THE WAY IT COULD WORK
✗ A driver's skills are invisible beyond their current employer	✓ Every qualification, every verified record travels with the driver across every employer
✗ Operators rebuild verification from scratch for every hire	✓ Verified records available instantly. No certificates to chase. No calls to make.
✗ Cities set electrification targets without knowing if the workforce is ready	✓ The city sees its workforce in aggregate. Skills gaps visible before they become crises.
✗ Training institutes produce qualified candidates with no route to operators	✓ Training credentials flow directly into the hiring layer. Qualified candidates discoverable immediately.
✗ Driving offers no visible career path for young people	✓ Skill recognised, rewarded, and worth investing in. Driving becomes a profession worth choosing.

HOW WOULD THIS WORK

01 THE DRIVER BUILDS A VERIFIED RECORD ONCE

Training completed, license validity, employment history, compliance checks, medical fitness. Each element verified by the institute, employer, or authority that issued it. The driver owns the record. It travels with them to every employer, in every city, for the duration of their career.

Driver owns the record | **Verified at source** | **Travels everywhere**

02 EVERY OPERATOR ACCESSES WHAT THEY NEED WITHOUT REBUILDING IT

An operator searching for EV-certified drivers filters by license type, training, and experience. Verified records are immediately available. No certificates to chase. No previous employers to call. No instinct-based decisions. The operator moves to hiring the same day.

No repeated verification | **Hire with confidence** | **Same day decisions**

03 THE CITY SEES ITS WORKFORCE FOR THE FIRST TIME

When every driver's credentials are on a shared layer, the city gains an aggregate picture of its mobility workforce. Where EV-certified drivers are concentrated. Where skills gaps exist. Whether the workforce is ready for the transition being planned. Policy becomes testable before targets are missed. This shared layer is also what makes agentic AI possible at city scale.

Workforce visible in aggregate | **Skills gaps surfaced early** | **Agents act autonomously**

UNLOCKING USE CASES NOBODY PLANNED

WHO	THE MOMENT	WHAT BECOMES POSSIBLE
 Driver	<i>Skills built over years</i>	Every qualification, employment record, and compliance check is verified and portable. Skill commands recognition, bargaining power, and better pay across every employer.
 Operator	<i>Driver vacancy open</i>	Verified candidates are discoverable immediately. No risky hires. Trusted onboarding. Lower churn as drivers with portable records have reason to perform and stay.
 City Government	<i>Electrification target set</i>	Workforce readiness visible in aggregate across every operator. Skills gaps identified before they become crises.
 Traffic Enforcement	<i>Compliance review due</i>	Driver quality visible beyond license validity alone. Employment history, training, and conduct records accessible. Smarter enforcement targeted where the data shows it is needed. Integration with existing registries without rebuilding them.
 Insurer	<i>Fleet policy underwritten</i>	Driver risk differentiated by verified record, not assumption. Risk-based pricing becomes possible. Lower claims as operators hire with confidence and drivers are incentivised to maintain clean records.
 Training Institute	<i>Course completed</i>	Graduates discoverable by operators searching for their specific certification. Skills formalised as portable credentials from the moment of issue.
 Green Finance	<i>EV transition funded</i>	Verified workforce readiness data becomes evidence for green bond disbursement. Transition milestones grounded in actual capability, not projections.

WHAT THIS CHANGES

Driving becomes a profession worth choosing. When skill is visible and trusted, effort is rewarded. A driver who invests in training builds a record that travels with them and opens doors that

personal contacts cannot. Young people see a career path. Experienced drivers command what they have earned. The profession attracts rather than settling for whoever is available.

Every participant makes the network more valuable for everyone already in it. A training institute joins and its graduates become immediately visible to every operator searching for their certification. An operator joins and its hiring behaviour becomes a demand signal that shapes what training institutes teach. A driver joins and every subsequent employer benefits from the verification work already done. No coordination required. The value compounds automatically.

Agentic AI becomes possible when the infrastructure is shared. An agent working on behalf of an operator searches verified records, filters by license type, training, and location, and surfaces qualified candidates without human intervention. An agent working on behalf of a driver monitors the skills that operators are actively searching for and recommends training that would open new opportunities. An agent working on behalf of a city reads aggregate credential data and flags workforce readiness risks before transition timelines are missed. All of this is only possible when the underlying records are on a shared, open layer.

PT AS A SERVICE

PUBLIC TRANSPORT AS A SERVICE

Unlocking the Latent Mobility Assets of a City.

Every city has more mobility than it can see.

The Problem

A city transit agency is planning to buy new mini buses to address first and last mile gaps for the city's public transit network. Two streets away, a fleet of school buses sits idle for sixteen hours a day, every day school is not in session. The city does not know those buses exist as a resource. The school operator does not know the city needs them.

Context

Every city has mobility assets that are not utilised to their full potential. A school bus runs two peaks a day. A corporate shuttle serves fixed routes at fixed times. A logistics van delivers in the morning and returns empty. A tourist coach sits between tours. For the remaining hours, these assets cost money and generate nothing.

What looks like a shortage is often invisibility compounded by barriers. Even when operators want to make idle capacity available, insurance coverage and permits are tied to the primary purpose. Any secondary use requires a bilateral arrangement complex enough that it is almost never attempted.

The result is transport poverty in cities that are full of vehicles. Demand responsive transit, dispatching a vehicle where it is needed rather than running a fixed route half-empty, remains a planning aspiration precisely because the shared layer that would make it possible does not exist.

Today, each operator manages their asset for their primary purpose only:

- idle windows are absorbed as a fixed cost, not seen as an opportunity
- regulatory and insurance barriers make secondary use too complex to attempt
- the city has no picture of what assets exist on its streets outside formal public transit
- procurement decisions are made without knowing what stranded capacity already exists

Every city faces this problem. Every mobility operator is bearing this cost. And the city keeps buying what it already has.

THE INTEGRATION CHAIN

 City Authority →  School Bus Operator ↳ <i>Negotiates bilateral agreement for off-peak use</i>	CUSTOM
 School Bus Operator →  Permit Authority ↳ <i>Separate permit required for commercial passenger use</i>	CUSTOM
 Permit Authority →  Payment System ↳ <i>Custom fare collection and settlement per arrangement</i>	CUSTOM
 Payment System →  Discovery / Booking ↳ <i>No shared visibility. Passengers cannot find or book the service.</i>	CUSTOM

THE COST OF THIS APPROACH

Capital trapped in idle assets Every vehicle sitting unused is a capital investment generating nothing. Insurance, maintenance, depreciation, and driver costs continue regardless. The idle	Regulatory barriers prevent secondary use Insurance coverage and permits are tied to primary purpose. Any secondary use requires a bilateral arrangement complex	The city procures what it already has Without visibility into stranded capacity, procurement decisions are made against an incomplete picture of supply. Cities spend on
--	--	--

window is a waste that every operator bears alone.	enough that it is almost never attempted. The policy infrastructure to enable shared use does not exist.	new assets to solve problems that existing assets, if visible and available, could already solve.
--	--	---

What If?

Every mobility asset in a city, school buses, corporate shuttles, tourist coaches, logistics vans, informal operators, could publish their available windows once. Any compliant asset can serve city demand. Any city demand can reach any compliant asset. Neither needs to know the other exists in advance.

TODAY	THE WAY IT COULD WORK
✗ A school bus sits idle for sixteen hours a day	✓ Idle windows published once. Demand arrives. The asset earns outside its primary purpose.
✗ A corporate shuttle returns empty on routes where demand exists	✓ Available windows discoverable. Any traveller on that corridor can book the return leg.
✗ The city procures new buses without knowing what exists on its streets	✓ Every asset visible in aggregate. Procurement decisions grounded in what is already there.
✗ Informal operators serve demand the city cannot see or plan around	✓ Informal operators discoverable, bookable, and able to receive digital payments. They appear on the city's mobility map for the first time.
✗ Any secondary use requires a bilateral agreement built from scratch	✓ Any operator publishes available windows once. Any platform can surface them. No bilateral agreements.

HOW WOULD THIS WORK

01 EVERY OPERATOR PUBLISHES WHAT THEY HAVE, WHEN THEY HAVE IT

A school bus operator lists the hours their fleet is not in service. A corporate shuttle operator lists the windows between employee runs. A tourist coach lists the gap between morning and evening tours. From that moment, every platform, every traveller, and every city service can find and use that capacity. No bilateral agreement. No separate permit negotiation.

Any asset | Any window | Any city

02 — THE RULES TRAVEL WITH THE ASSET, NOT THE AGREEMENT

The city sets the conditions for secondary use once — which assets qualify, what safety requirements apply, what insurance is required. Every time a compliant asset is activated outside its primary purpose, the right permit, insurance, and safety conditions are triggered instantly. No separate permit. No new negotiation..

City sets the rules | Triggered instantly | No new agreement

03 — AVAILABLE CAPACITY FINDS UNMET DEMAND, AUTOMATICALLY

Every asset that publishes an available window becomes visible. Every unmet demand signal becomes actionable. AI agents match the two, across the city, in real time. A school bus with three free hours finds the commuters who need it. A city with a peak hour spike finds the fleet that can serve it. No phone calls. No manual coordination.

Full supply visible | Demand matched in real time | Agents act autonomously

Scenarios

- A city that was about to procure thirty new buses discovered it had equivalent capacity sitting idle in school fleets and corporate shuttles.
- A school operator that saw idle capacity as a fixed cost discovered it could generate revenue from off-peak hours without changing its primary operations.

- A transit authority that struggled with first and last mile gaps discovered that informal operators in those corridors were already serving the demand, and brought them onto the shared layer to make them bookable as an end-to-end journey.
- A city responding to a flood emergency discovered it could deploy every school bus, corporate shuttle, and logistics van in the affected area within hours.
- A microfinance institution that struggled to assess risk for informal operators discovered it could use verified trip records from the shared layer as a credit signal.

UNLOCKING USE CASES NOBODY PLANNED

WHO	THE MOMENT	WHAT BECOMES POSSIBLE
 City Government	<i>Peak demand exceeds capacity</i>	Idle capacity across every operator on the city's mobility network available to meet demand. Fleet operators plug in when the city needs them. Service standard set once, applied automatically across every asset on the network, including those the city does not own. The network scales with demand.
 Dedicated Fleet Operator	<i>Fleet sitting idle</i>	School buses, corporate shuttles, and institutional vehicles with available windows published once. City demand arrives without a new contract. The fleet earns revenue from capacity already being paid for, during hours that previously generated nothing.
 Informal Operator	<i>Serving demand no one can see</i>	Discoverable, bookable, and able to receive digital payments for the first time. Demand the city could not plan around becomes demand the city can rely on and policy can respond to.
 Insurer	<i>Fleet policy underwritten</i>	Usage-based insurance for secondary use becomes possible. The right coverage applied automatically when an asset moves outside its primary purpose window. Priced to actual risk, not assumed worst case.
 Traveller	<i>Searching for a ride</i>	Every available vehicle on the corridor, formal transit, school buses, corporate shuttles, informal operators, visible in one search. Public transit becomes reliable - Fewer gaps, fewer waits, fewer missed connections.
 Emergency Responder	<i>Crisis declared</i>	Every available mobility asset in the affected area deployable through one shared layer. No bilateral calls. No coordination from scratch. The city's full mobility supply activated in hours.
 Green Finance	<i>Emissions target set</i>	Idle capacity reduction, modal shift, and informal operator formalisation all measurable and reportable as climate outcomes. Green bond disbursement tied to actual performance, not projections.
 Microfinance / Lender	<i>Operator seeks credit</i>	Verified trip history, utilisation patterns, and asset performance data on a shared layer become a credit signal. An informal operator with three years of verified clean trip records can access financing for a second vehicle..

WHAT THIS CHANGES

Informal becomes part of the formal without losing autonomy. Invisible operators become visible. Their demand becomes legible. Their capacity becomes plannable. The city's network finally reflects how its people actually move.

The city's mobility supply stops being fixed and starts being alive. It expands when demand rises. It contracts when it falls. The city never builds for the worst case again.

The city gains intelligence it never had. Every asset, every demand signal, every gap visible simultaneously. Decisions that required human coordination at every step now happen continuously and automatically across the entire network.

EV Charging

EVERY EV. EVERY CHARGER. STILL AN ISLAND.

Moving and Powering the City on One Shared Layer.

Cities are electrifying their mobility. The infrastructure to support it is being built in fragments.

The Problem

A city is electrifying its mobility. EVs are arriving across every segment, public transit, shared mobility, logistics, and personal transport. The charging infrastructure to support them is being built network by network, with no shared picture of where demand will be, which areas will go unserved, or whether the grid will hold.

Context

The problem spans every actor in the city's mobility ecosystem:

Fragmentation

- a mobility operator (shared mobility, public transport etc.) managing an electric fleet sign separate agreements with every charge point operator in every city it serves, with no unified view of coverage, availability, or cost

Invisibility

- a city allocating scarce kerb space has no visibility into where demand will actually be across all charge point operators, making every allocation a guess
- charge point operators and battery swap stations are placed by individual operator estimates, not verified demand, leaving some locations oversupplied and others without coverage
- uncoordinated peak charging puts pressure on aging grid infrastructure, creating the risk of local instability city officials are directly accountable for

Inequity

- private charge point operators cluster infrastructure where commercial returns are highest, leaving lower-income areas without reliable access
- an electric bus or shared mobility fleet that cannot charge reliably becomes a service gap in the communities that depend on it most

Every actor is solving their piece of the problem alone. The city sees the transition happening. It cannot see whether it is working for everyone.

THE INTEGRATION CHAIN

 Mobility Operator →  Charge Point Networks ↳ Signs separate proprietary agreements with every network. Each gives access to its chargers only. No single agreement covers the city.	CUSTOM
 EV arrives at charger → Wrong network ↳ Charger rejects the vehicle. Driver downloads a new app, creates a new account, pays separately.	CUSTOM
 All Networks →  City / Grid ↳ No shared demand data. Charger utilisation, battery swap capacity, and peak load invisible to city planners and grid operators.	CUSTOM

THE COST OF THIS APPROACH

Every charger is an island Each charging network operates independently. A vehicle from one operator cannot charge on another network without a separate agreement, a separate app, and a separate payment.	Infrastructure built by guesswork Charge point operators invest without a system-wide picture of demand. Some locations are oversupplied. Others have no coverage. Battery swap stations face the same problem.	Communities left behind Private operators follow commercial returns. Lower-income areas and underserved communities get chargers last, if at all. The transition does not reach everyone at the same pace.
---	---	--

What If?

Every energy asset and every mobility asset in a city, a charging station, a solar rooftop, a parked vehicle, a building battery, an electric bus, could discover each other, transact directly, and settle automatically on one shared layer.

TODAY	THE WAY IT COULD WORK
✗ A mobility operator is locked to its own charging network	✓ Any compliant EV charges at any charger on any network. One transaction. No bilateral agreement.
✗ Charge point operators invest without knowing where demand will be	✓ System-wide demand data guides where infrastructure is built. Investment follows verified need, not guesswork.
✗ Battery swap stations placed by individual operator estimates	✓ Every swap station visible in aggregate. Placement follows verified demand across all operators.
✗ Lower-income areas served last by private operators	✓ City sets equity requirements once. They apply automatically across every charge point operator.
✗ Grid absorbs uncoordinated peak charging with no advance signal	✓ Every charge event on record. Grid operators see aggregate demand in real time across every fleet.

HOW WOULD THIS WORK

01 DISCOVERY AND ACCESS, OPEN TO ALL

Any charge point operator lists their chargers once on their own terms. Any compliant EV discovers, accesses, and settles on any listed charger. No bilateral agreement. No proprietary app.

Any EV | **Any charger** | **Any network**

02 DEMAND GUIDES WHERE INFRASTRUCTURE IS BUILT

Every charge event becomes a demand signal. Charge point operators invest where the data shows they are needed. Cities plan against verified demand, not projections. Equity requirements travel automatically across every operator.

Demand visible in aggregate | **Investment follows need** | **Equity built in**

03 THE PARKED EV BECOMES A GRID ASSET

A parked EV is a battery. Energy providers discover available capacity, offer a price, and settle automatically. The fleet earns from parked vehicles. The grid stabilises without new infrastructure.

V2G activated | **Energy arbitrage enabled** | **Distributed storage**

04 AGENTS ACT ON BEHALF OF EVERY PARTICIPANT

An agent working for a fleet operator optimises when and where each vehicle charges and when it returns energy to the grid. An agent working for a city dispatches V2G capacity before a grid stress

event becomes a crisis. Neither waits for a human instruction. Both are only possible when every vehicle, every charger, and every energy signal is visible on the same layer.

Autonomous | Real time | No human intervention at each step

Scenarios

- A charge point operator that wanted to expand its network discovered it could identify the highest-demand locations across the entire city's EV fleet before committing a single investment.
- A bus operator that wanted to reduce energy costs discovered its parked overnight fleet could return energy to the grid during morning peak demand and earn revenue it had never accounted for.
- A city that wanted to meet its grid stability targets during summer peaks discovered it had a distributed battery network in its EV fleets that could be activated without building a single new energy storage facility.
- A green bond issuer that needed verified emissions reduction data discovered it could draw directly on charge event records, making the bond issuance faster and the audit trail irrefutable.

None of these were designed in. They became possible because the infrastructure was available to all.

UNLOCKING USE CASES NOBODY PLANNED

WHO	THE MOMENT	WHAT BECOMES POSSIBLE
 Fleet Operator	<i>Vehicle needs charging</i>	Discovering any charger on any network. No locked-in agreements. Charging costs reduced through AI-optimised scheduling against real-time energy prices. Parked vehicles earn through V2G participation.
 Charge Point Operator	<i>New location planned</i>	Charger utilisation maximised because placement follows verified need. Revenue increased as any EV on any network can access their infrastructure.
 Energy Provider	<i>Grid demand peaks</i>	Advance signal of aggregate EV charging demand across every fleet. V2G capacity discoverable and dispatchable. Grid stabilised using distributed storage already in the city's parked vehicles.
 Climate Fund / Investor	<i>Outcome verification needed</i>	Verified charge event data proves the transition is delivering. Carbon credits generated automatically. Climate funds disburse against proof. The city accesses cheaper capital because it can demonstrate what it promised.
 Prosumers – (Resident with Solar Rooftop)	<i>Surplus energy generated</i>	Surplus solar sold directly to a shared mobility fleet charging nearby. Neither planned for the other. The resident receives mobility vouchers in return. Their energy pays for their city transport.
 Low-Income Resident	<i>Energy credit issued</i>	Energy credits issued as welfare redeemable against charging costs or convertible to mobility vouchers. The same shared layer that settles energy transactions distributes access without a separate programme.
 Street / Municipality	<i>EVs parked overnight</i>	Parked EVs push energy back through V2G to power street lighting. The vehicles that consumed energy during the day return it at night. The street's energy infrastructure becomes self-financing.
 City as Energy Exporter	<i>Surplus at midday</i>	Surplus energy from solar and charged EV batteries flows to neighbouring regions via the grid. Settled automatically. The city earns from energy it would otherwise have curtailed.

WHAT THIS CHANGES

The boundary between mobility and energy dissolves. Every vehicle is also a battery. Every charger is also a grid asset. Two systems that were designed, built, and regulated separately become one.

The city becomes a participant in its own energy market. Not just a regulator or a consumer. A city with EVs, solar, and shared infrastructure can produce, store, and trade energy. The transition it committed to starts paying for itself.

Invisible assets become productive. A parked vehicle. A solar rooftop. A building battery. Assets that existed but could not find demand now participate in a market automatically.

Every new participant strengthens the whole. The network does not need to be designed for every use case. It creates the conditions for use cases nobody imagined. Each new asset makes every other asset more valuable.

Intelligence moves from humans to agents. The decisions that required phone calls, bilateral negotiations, and manual coordination now happen continuously and automatically. The infrastructure does not just connect. It acts.
